Abstract

The binary Mumford-Shah model is a widespread tool for image segmentation and can be considered as a basic model in shape optimization with a broad range of applications in computer vision, ranging from basic segmentation and labeling to object reconstruction. This paper presents robust a posteriori error estimates for a natural error quantity, namely the area of the non-properly segmented region. To this end, a suitable uniformly convex and non-constrained relaxation of the originally non-convex functional is investigated and Repin’s functional approach for a posteriori error estimation is used to control the numerical error for the relaxed problem in the $L^2$-norm. In combination with a suitable cut out argument, fully practical estimates for the area mismatch are derived. This estimate is incorporated in an adaptive mesh refinement strategy. Two different adaptive primal-dual finite element schemes, a dual gradient descent scheme, and the most frequently used finite difference discretization are investigated and compared. Numerical experiments show qualitative and quantitative properties of the estimates and demonstrate their usefulness in practical applications.

1 Introduction

Since the introduction of the image denoising and edge segmentation model by Mumford and Shah in the late 80’s [35], there has been much effort to find effective and efficient numerical algorithms to compute minimizers of different variants of this variational problem. The original model is based on the functional $E_{\text{MS}}[u, K] = \int_{\Omega \setminus K} |\nabla u|^2 + \alpha(u - u_0)^2 \, dx + \beta \mathcal{H}^{n-1}(K)$ with $\alpha, \beta > 0$, where $u_0 \in L^\infty(\Omega, [0, 1])$ is a scalar image intensity on the bounded image domain $\Omega \subset \mathbb{R}^n$, $u$ the reconstructed image intensity and $K$ the associated set of edges, on which the image intensity $u$ jumps. Here, $\mathcal{H}^{n-1}$ denotes the $(n-1)$-dimensional Hausdorff measure. The space of functions of bounded variation $BV(\Omega)$ turned out to be the proper space to formulate the problem in a mathematical rigorous way. Indeed, existence in the context of the space of special functions of bounded variation $SBV(\Omega)$ was proved by Ambrosio (see [2, Theorem 4.2]). For details on these spaces we refer to [3]. Restricting $u$ to be piecewise constant instead of piecewise smooth, one is lead to a basic and widespread image segmentation model. This model is discussed from a geometric perspective in the book by Morel and Solimini [34]. In the case of just two intensity values $c_1, c_2 \in [0, 1]$, the associated energy can be rewritten in terms of a characteristic function $\chi \in BV(\Omega, \{0, 1\})$ as

\[ E[\chi] = \int_\Omega \theta_1 \chi + \theta_2 (1 - \chi) \, dx + |D\chi|(\Omega). \]  (1.1)
Here, \( \theta_i = \frac{1}{2}(c_i - u_0)^2 \) for \( i = 1, 2 \), the new weight \( \nu = \beta/\alpha \) and the resulting binary model is given by \( u = c_1 \chi + c_2(1 - \chi) \). For fixed \( \chi \), one immediately obtains the optimal constants

\[
    c_1[\chi] = \left( \int_\Omega \chi \, dx \right)^{-1} \int_\Omega \chi u_0 \, dx \quad \text{and} \quad c_2[\chi] = \left( \int_\Omega (1 - \chi) \, dx \right)^{-1} \int_\Omega (1 - \chi) u_0 \, dx . \tag{1.2}
\]

For fixed \( c_1 \) and \( c_2 \), one aims at minimizing the energy over the non-convex set of characteristic functions \( \chi \in \text{BV}(\Omega, \{0, 1\}) \). In the general case, one is interested in a triple \((\chi, c_1, c_2)\) as a minimizer of \( E \) w.r.t. the set \( \text{BV}(\Omega) \times [0, 1]^2 \). Henceforth, if not otherwise stated we assume the intensity values to be fixed.

Nikolova, Esedoglu and Chan [36] showed that the non-convex minimization problem for \( \chi \) can be solved via relaxation and thresholding—a breakthrough for both reliable and fast algorithms in computer vision [40, 17]. Here, at first one asks for a minimizer of \( E \) over all \( u \in \text{BV}(\Omega, \{0, 1\}) \) and then thresholds \( u \) for any threshold value \( s \in [0, 1) \) to obtain the solution \( \chi = \chi_{[u>s]} \) of the original minimization problem. The relaxed problem coincides with a constrained version of the classical image denoising model by Rudin, Osher and Fatemi (ROF) [45]. Numerical schemes for an effective and efficient minimization of this model have extensively been studied. Making use of a dual formulation, Chambolle [14] introduced an iterative finite difference scheme and proved its convergence. Hintermüller and Kunisch [30] proposed a preduall formulation for a generalized ROF model and applied a semismooth Newton method for a regularized variant. Chambolle and Pock [20] deduced a primal-dual algorithm with guaranteed first order convergence and applied their approach to different variational models in BV such as image denoising, deblurring and interpolation. The scheme is based on an alternating discrete gradient scheme for the discrete primal and the discrete dual problem. Bartels [6] used the embedding \( \text{BV}(\Omega) \cap L^\infty(\Omega) \to H^1(\Omega) \) to improve the step-size restriction for BV functionals. Wang and Lucier [47] employed a finite difference approximation of the ROF model and derived an a priori error estimate for the discrete solution based on suitable projection operators. Following Dobson and Vogel [23], the total variation regularization can be approximated smoothly via \( \sqrt{|\nabla u|^2 + \epsilon} \). In [26], the convergence of the \( L^2 \)-gradient flow of this smooth approximation to the TV flow in \( L^2 \) is shown under strong regularity assumptions on the solution.

Furthermore, approximations of the original Mumford-Shah model have been studied extensively. An early overview of different approximation and discretization strategies was given by Chambolle in [13]. Ambrosio and Tortorelli [4] proposed a phase field approximation of this functional and proved its \( \Gamma \)-convergence. Chambolle and Dal Maso [18] proposed a discrete finite element approximation and established its \( \Gamma \)-convergence. Bourdin and Chambolle [9] picked up this approach and studied the generation of adaptive meshes iteratively adapted in accordance to an anisotropic metric depending on the current approximate solution. In [46], Shen introduced a \( \Gamma \)-converging approximation of the piecewise constant Mumford-Shah segmentation, where the length term in the Mumford-Shah model is approximated via an approach originating from the phase field model by Modica and Mortola [33]. A simple and widespread level set approach was proposed by Chan and Vese [21].

The goal of this paper is to derive a posteriori error estimates for the characteristic function \( \chi \). To this end, we proceed as follows: We take into account a suitable uniformly convex relaxation of the binary Mumford-Shah functional already studied in [8], which is related to more general relaxation approaches suggested by Chambolle [15] and does not require any constraint in the minimization. For this relaxation, we consider its preduall and set up a corresponding primal-dual algorithm [5, 20, 29]. Then, following Bartels [5], we use Repin’s primal-dual approach [42, 43] to derive functional a posteriori error estimates for the relaxed solution based on upper bounds of the duality gap (cf. also the book by Han [28] with respect to mechanical applications) (see Section 2). These estimates can be used together with a suitable cut out argument to derive an a posteriori estimate for the characteristic function \( \chi \) minimizing the original functional (1.1). In addition, a sensitivity analysis of \( \chi \) depending on \( c_1, c_2 \) and of \( c_1, c_2 \) depending on \( \chi \) is studied (see Section 3). Moreover, two adaptive finite element discretization schemes and one conventional, non adaptive
finite difference scheme are investigated (see Section 4). Based on these discretization schemes, a primal-dual algorithm and a dual gradient descent are introduced in Section 5. Finally, we apply the resulting estimate to these schemes incorporating an appropriate post smoothing and present the numerical results (see Section 6).

2 Uniformly Convex Relaxation and Functional Error Estimates

Henceforth, we use the notation $\chi_A$ to denote the indicator function of a measurable set $A \subset \Omega$ and define $[u > c] := \{x \in \Omega : u(x) > c\}$. We use generic constants $c$ and $C$ throughout this paper. Furthermore, if not stated otherwise, we assume the intensity values $c_1$ and $c_2$ to be fixed with $c_1, c_2 \in [0, 1]$ and $c_1 \neq c_2$. Rewriting the binary Mumford-Shah functional (1.1) as

$$E[\chi] = \int_{\Omega} (\theta_1 - \theta_2) \chi \, dx + |D\chi|($$

one observes that adding a constant to $\theta_1$ and $\theta_2$ leaves the minimizers $\chi$ unchanged. Thus, we may assume that $\theta_1, \theta_2 \geq c > 0$. Let us introduce the following relaxed functional

$$E^{rel}[u] = \int_{\Omega} u^2 \theta_1 + (1-u)^2 \theta_2 \, dx + |Du|(\Omega),$$

which is supposed to be minimized over all $u \in BV(\Omega, \mathbb{R})$. Indeed, $E^{rel}[\chi] = E[\chi]$ for characteristic functions $\chi$ and one retrieves the original binary Mumford-Shah model. Proving existence of minimizers of (2.2) via the direct method in the calculus of variations is straightforward, for details we refer to [3, 25]. Furthermore, (2.2) is uniformly convex by our above assumptions on $\theta_1$ and $\theta_2$. Loosely speaking, a preference for the values 0 and 1 for $u$ is encoded in the quadratically growing data term. The minimizers of both functionals (1.1) and (2.2) are related in the following sense (cf. [8]):

**Proposition 2.1** (Convex relaxation and thresholding). **Under the above assumptions, a minimizer $u \in BV(\Omega)$ of the functional $E^{rel}$ exists, $u(x) \in [0, 1]$ for a.e. $x \in \Omega$ and**

$$\chi_{[u>0.5]} \in \arg\min_{\chi \in BV(\Omega, \{0,1\})} E[\chi].$$

Proposition 2.1 is an instance of a more general result, which can be found in [15, 19, 31]. In fact, let $\Psi : \Omega \times \mathbb{R} \to \mathbb{R}$ be measurable, $\Psi(\cdot, t) \in L^1(\Omega)$ for a.e. $t \in \mathbb{R}$, $\Psi(x, \cdot) \in C^1(\mathbb{R})$ be strictly convex for a.e. $x \in \Omega$, $\Psi(x, t) \geq ct|t| - C$ and $E_{\Psi}[u] = \int_{\Omega} \Psi(x, u) \, dx + |Du|(\Omega)$. Then, there exists a minimizer $u \in \arg\min_{\chi \in BV(\Omega)} E_{\Psi}[\chi]$ and for $s \in \mathbb{R}$

$$\chi^s := \chi_{[u>s]} \in \arg\min_{\chi \in BV(\Omega, \{0,1\})} \int_{\Omega} \partial_t \Psi(x, s) \chi \, dx + |D\chi|(\Omega).$$

For $\Psi(x, t) = t^2 \theta_1(x) + (1-t)^2 \theta_2(x)$ the property $u(x) \in [0, 1]$ follows directly when comparing with the energy of the function $\min(1, \max(0, u))$. Furthermore, choosing $s = \frac{1}{2}$ allows to verify the main claim of Proposition 2.1. Indeed, for $t \in \mathbb{R}$ and $\chi \in BV(\Omega, \{0,1\})$, let $E^{rel}_t[\chi] := \int_{\Omega} \partial_t \Psi(x, t) \chi \, dx + |D\chi|(\Omega)$. For our specific choice of $\Psi$,

$$E^{rel}_t[\chi] = \int_{\Omega} (2t(\theta_1(x) + \theta_2(x)) - 2\theta_2(x)) \chi \, dx + |D\chi|(\Omega)$$

implies that minimizing the functional $E^{rel}_t$ is equivalent to minimizing the functional $E$ because $E^{rel}_t[\chi] = E[\chi] - \int_{\Omega} \theta_2 \, dx$. 

3
Remark. The particular advantage of our model compared to the relaxation approach by Nikolova, Esedoglu and Chan [36] is that the relaxed problem has not to be constrained to functions \( u \) with values in \([0, 1]\). One could also consider a ROF type functional choosing \( \Psi(x, t) = \frac{1}{2} (t - (\theta_2(x) - \theta_1(x)))^2 \) (cf. [7]) and obtain the functional \( E_0^{\text{rel}}(\chi) \) for the threshold value \( s = 0 \), but in this case the \( L^\infty \) bound of the relaxed solution depends on the \( L^\infty \) bounds of \( \frac{1}{2} (c_i - u_0)^2 \) (cf. Proposition 2.1) and requires a more involved cutoff scheme (see Section 3).

In what follows, we make use of convex analysis to derive a duality formulation for the minimization problem of the relaxed functional (2.2) and derive functional a posteriori estimates for this problem. Primal and dual formulation will be later used in the a posteriori estimates. The dual of \( BV(\Omega) \) is very difficult to characterize and not suitable for computational purposes. Thus, for a generalized ROF model Hintermüller and Kunisch [29] proposed to consider the corresponding BV functional as the dual of another functional, which we refer to as the predual functional. Bartels [5] made use of this approach in the context of a posteriori estimates for the ROF model. Here, we follow this procedure and investigate the predual of (2.2).

Recall that the Fenchel conjugate \( J^* \) of a functional \( J: X \to \mathbb{R} \) on a Banach space \( X \) with \( \mathbb{R} = RU(\infty) \) is a functional on the dual space \( X' \) with values in \( \mathbb{R} \), defined as \( J^* (x') = \sup_{x \in X} \{ \langle x', x \rangle - J(x) \} \), where \( \langle \cdot, \cdot \rangle \) denotes the duality pairing. Furthermore, we denote by \( \Lambda^* \in \mathcal{L}(Y', Y') \) the adjoint operator of \( \Lambda \in \mathcal{L}(X, Y) \) and by \( \partial J \) the subgradient of \( J \) (cf. [24]).

Now, we investigate an energy functional

\[
D^{\text{rel}}[q] = F[q] + G[\Lambda q] \quad q \in \mathcal{Q} \quad (2.3)
\]

with \( F: \mathcal{Q} \to \mathbb{R} \) and \( G: \mathcal{V} \to \mathbb{R} \) being proper, convex and lower semicontinuous functionals, \( \mathcal{V} \) and \( \mathcal{Q} \) being reflexive Banach spaces and \( \Lambda \in \mathcal{L}(\mathcal{Q}, \mathcal{V}) \). In our case, the predual of the convex relaxed binary Mumford-Shah model is given by

\[
F[q] = \mathcal{I}_{B_1}[q] = \begin{cases} 
0 & \text{if } |q| \leq 1 \ \text{a.e.,} \\
+\infty & \text{else}
\end{cases} \quad \text{and} \quad G[v] = \int_{\Omega} \frac{1}{2} \nu^2 + v \theta_2 - \theta_1 \theta_2 \quad \text{d}x,
\]

with \( \Lambda = \text{div}, \mathcal{Q} = H_N(\text{div}, \Omega) \) and \( \mathcal{V} = L^2(\Omega) \). Recall the definition of the spaces \( H(\text{div}, \Omega) = \{ q \in L^2(\Omega, \mathbb{R}^n) : \text{div } q \in L^2(\Omega) \} \), endowed with the norm \( \| q \|^2_{H(\text{div}, \Omega)} = \|\text{div } q\|^2_{L^2(\Omega)} + \|q\|^2_{L^2(\Omega)} \), and \( H_N(\text{div}, \Omega) = H(\text{div}, \Omega) \cap \{ q \cdot \nu = 0 \text{ on } \partial \Omega \} \), where \( \nu \) is the outer normal on \( \partial \Omega \) and the operator \( \text{div} \) is understood in the weak sense. Moreover, \( \Lambda^* = -\nabla \) holds in the sense

\[
(\Lambda^* v, q)_{L^2(\Omega)} = (v, \text{div } q)_{L^2(\Omega)} \quad \forall v \in \mathcal{V}, \ q \in \mathcal{Q}.
\]

Based on this duality and for the particular choice of \( D^{\text{rel}} \), we easily verify that \( (D^{\text{rel}})^* = E^{\text{rel}} \). Indeed, from the general theory in [24, pp. 58 ff.], we can deduce \( (D^{\text{rel}})^*[v] = F^*[-\Lambda^* v] + G^*[v] \).

As a result of the denseness of \( C^1_c(\Omega) \) in \( H_N(\text{div}, \Omega) \) with respect to the norm \( \| \cdot \|_{H(\text{div}, \Omega)} \), we can infer for any \( v \in BV(\Omega) \)

\[
|Dv|(\Omega) = \sup_{q \in \mathcal{Q}, \| q \|_{\infty} \leq 1} \int_{\Omega} v \text{div } q \quad \text{d}x = \sup_{q \in \mathcal{Q}} \left( - \int_{\Omega} v \text{div } q \quad \text{d}x - I_{\mathcal{I}_{B_1}}[q] \right),
\]

which leads to

\[
F^*[-\Lambda^* v] = \sup_{q \in \mathcal{Q}} \left( - \int_{\Omega} v \text{div } q \quad \text{d}x - I_{\mathcal{I}_{B_1}}[q] \right) = |Dv|(\Omega).
\]

On the other hand, the Fenchel conjugate of \( G \) can be computed as follows:

\[
G^*[v] = \sup_{w \in L^2(\Omega)} \left( (v, w)_{L^2(\Omega)} - G[w] \right) = \int_{\Omega} v^2 \theta_1 + (1 - v)^2 \theta_2 \quad \text{d}x,
\]

where the supremum is attained for \( w = 2v(\theta_1 + \theta_2) - 2\theta_2 \). This verifies the assertion.
The central insight is that
\[ D_{\text{rel}}[p] = -(D_{\text{rel}})^*[u] \] (2.4)
for a minimizer \( p \) of \( D_{\text{rel}} \) and a minimizer \( u \) of \((D_{\text{rel}})^*\). A rigorous verification can be found in [24, Chapter III.4] (see also [44, 42, 5]). Furthermore, one obtains that \( \bar{v} \in Q \) and \( \bar{v} \in \mathcal{V} \) are optimal if and only if \(-\Lambda^* \bar{v} \in \partial F[\bar{q}] \) and \( \bar{v} \in \partial G[\Lambda q] \), which can be deduced from the equivalence \( J[x] + J^*[x'] = \langle x', x \rangle \iff x' \in \partial J[x] \) (see [24, Proposition I.5.1]).

In what follows, we investigate the posteriori error estimates associated with the energy \( D_{\text{rel}}[q] = F[q] + G[\Lambda q] \) and its dual \( E_{\text{rel}}[v] = F^*[-\Lambda^* v] + G^*[v] \) (for fixed intensity values \( c_1 \) and \( c_2 \)). A crucial prerequisite is the uniform convexity of \( G^* \), which is linked to the specific choice of the relaxed Model \( E_{\text{rel}} \).

Recall that a functional \( J : X \to \mathbb{R} \) is uniformly convex, if there exists a continuous functional \( \Phi_J : X \to [0, \infty) \) such that \( J\left(\frac{x_1 + x_2}{2}\right) + \Phi_J(x_2 - x_1) \leq \frac{1}{2}(J[x_1] + J[x_2]) \) for all \( x_1, x_2 \in X \) and \( \Phi_J(x) = 0 \) if and only if \( x = 0 \). Furthermore, we denote by \( \Psi_J \) a non-negative functional such that \( \langle x', x_2 - x_1 \rangle + \Psi_J(x_2 - x_1) \leq J[x_2] - J[x_1] \) for all \( x' \in \partial J[x_1] \). Hence, \( \Psi_J \) allows a quantification of the strict monotonicity of \( J \). If \( J \in C^2 \) and \( \lambda_{\text{min}} \) denotes the smallest eigenvalue of \( D^2 J \), then \( \Phi_J \) and \( \Psi_J \) admit the representation \( \Phi_J(x) = \frac{1}{8} \lambda_{\text{min}}(D^2 J)[x]^2 \) and \( \Psi_J(x) = \frac{1}{2} \lambda_{\text{min}}(D^2 J)[x] \), which follows readily via a Taylor expansion.

Remark. The optimal \( \Psi_J^* \) coincides with the Bregman distance (cf. [11]), i.e.
\[ \Psi_J^*(x_2 - x_1) \leq \Psi_J^*(x_2 - x_1) := J[x_2] - J[x_1] - \sup_{x' \in \partial J[x_1]} \langle x', x_2 - x_1 \rangle \]
for any other \( \Psi_J \) and \( x_1, x_2 \in X \).

Now, the a posteriori error estimate is based on the following direct application of a general result by Repin [42]: Let \( u \in \text{argmin}_{v \in \mathcal{V}} E_{\text{rel}}[\bar{v}] \) and \( q \in \mathcal{Q}, v \in \mathcal{V}' = \mathcal{V}' = L^2(\Omega) \). Then,
\[ \Phi_{G^*}(v - u) + \Phi_{F^*}(-\Lambda^*(v - u)) + \Psi_{E_{\text{rel}}}[v] \left(\frac{v - u}{2}\right) \leq \frac{1}{2}(E_{\text{rel}}[v] + D_{\text{rel}}[q]) \] (2.5)
The proof of (2.5) relies on the above strict convexity estimates and the fundamental relation \( E_{\text{rel}}[u] \geq -D_{\text{rel}}[q] \) known as the weak complementarity principle [24], and can be found in [42, 5].

In the case of the binary Mumford-Shah model, we easily verify that
\[ \Phi_{F^*} \equiv 0, \quad \Phi_{G^*}(v) = \frac{1}{4} \int_{\Omega} v^2(\theta_1 + \theta_2) \, dx, \quad \Psi_{E_{\text{rel}}}(v) = \int_{\Omega} v^2(\theta_1 + \theta_2) \, dx , \]
and the estimate (2.5) implies for any \( v \in \mathcal{V} \) and \( q \in \mathcal{Q} \)
\[ \int_{\Omega} (u - v)^2(\theta_1 + \theta_2) \, dx \leq E_{\text{rel}}[v] + D_{\text{rel}}[q] . \]
Finally, \( \frac{1}{2}(a - b)^2 \leq a^2 + b^2 \) with \( a = c_1 - u_0 \) and \( b = c_2 - u_0 \) yields \( \frac{1}{2a}(c_1 - c_2)^2 \leq \theta_1 + \theta_2 \). Thus, we obtain the following theorem:

**Theorem 2.2.** Let \( u \in \mathcal{V} \) be the minimizer of \( E_{\text{rel}} \). Then, for any \( v \in \mathcal{V} \) and \( q \in \mathcal{Q} \) it holds that
\[ \|u - v\|^2_{L^2(\Omega)} \leq \text{err}_{\text{rel}}^2[u, v, c_1, c_2] := \frac{2\nu}{(c_1 - c_2)^2}(E_{\text{rel}}[v] + D_{\text{rel}}[q]) . \] (2.6)

In the application, one asks for the (post-processed) discrete primal \( v \) and dual solution \( q \) which ensure a small right hand side. Additionally, the estimator \( \text{err}_{\text{rel}} \) is consistent, i.e. \( \text{err}_{\text{rel}}[v, q, c_1, c_2] \to 0 \) provided \( v \) and \( q \) converge to the extrema of the corresponding energy functionals w.r.t. the topology of the associated Banach spaces.
3 A Posteriori Error Estimates for the Binary Mumford-Shah Model

In the sequel, we expand the a posteriori theory to the binary Mumford-Shah model. The key observation is that for many images approximate solutions \( u \in L^2(\Omega) \) of the relaxed model are characterized by steep profiles, where the actual solution of the original binary Mumford-Shah model jumps. We proceed as follows. We define

\[
a[v, \eta] = \left\| \chi_{[\frac{1}{2} - \eta \leq v \leq \frac{1}{2} + \eta]} \right\|_{L^1(\Omega)}
\]

for \( \eta \in (0, \frac{1}{2}) \), which measures the area of the preimage of the interval of size \( 2\eta \) centered at the threshold value \( s = \frac{1}{2} \) (cf. Section 2). Based on the above observation, the set \( S_\eta = \left[ \frac{1}{2} - \eta \leq v \leq \frac{1}{2} + \eta \right] \) can be regarded as the set of non-properly identified regions. Combining this definition with the thresholding argument presented in Proposition 2.1, we obtain the subsequent theorem:

**Theorem 3.1** (A posteriori error estimator for \( \chi \)). For fixed \( c_1 \) and \( c_2 \), let \( u \in BV(\Omega) \) and \( \chi = \chi_{[u > \frac{1}{2}]} \in BV(\Omega, \{0, 1\}) \) be a minimizer of the relaxed functional \( E^{\text{rel}} \) (see (2.2)) and the binary Mumford-Shah functional \( E \) (see (1.1)), respectively. Then for all \( v \in V = L^2(\Omega) \) and \( q \in Q = H_N(\text{div}, \Omega) \) we have that

\[
\left\| \chi - \chi_{[v > \frac{1}{2}]} \right\|_{L^1(\Omega)} \leq \text{err} \chi[v, q] := \inf_{\eta \in (0, \frac{1}{2})} \left( a[v, \eta] + \frac{1}{\eta^2} \text{err}_u^2[v, q, c_1, c_2] \right). \tag{3.1}
\]

Recall that \( \chi_{[v > \frac{1}{2}]} \) is the indicator function of the set \( [v > \frac{1}{2}] \). Let us remark that \( \chi_{[u > \frac{1}{2}]} \) is the result of the same thresholding, which relates \( \chi \) to the solution \( u \) of the relaxed problem (2.2), i.e. \( \chi = \chi_{[u > \frac{1}{2}]} \), this time applied to \( v \).

**Proof.** Any minimizer \( u \) of \( E^{\text{rel}} \) fulfills \( 0 \leq u \leq 1 \) and \( \chi_{[u > \frac{1}{2}]} \) minimizes \( E \) (see Proposition 2.1). For all \( \eta \in (0, \frac{1}{2}) \), we obtain the following set relation for the symmetric difference of the sets \( [u > \frac{1}{2}] \) and \( [v > \frac{1}{2}] \): \( \Delta \) denoting the symmetric difference of two sets:

\[
[u > \frac{1}{2}] \Delta [v > \frac{1}{2}] \subseteq \{ x \in \Omega | \frac{1}{2} - \eta \leq v(x) \leq \frac{1}{2} + \eta \} \cup \{ x \in \Omega | |u(x) - v(x)| > \eta \}. \tag{3.2}
\]

Now, using Theorem 2.2 the Lebesgue measure of the rightmost set can be estimated as follows

\[
\mathcal{L}^n([u - v] > \eta) \leq \int_{\{[u - v] > \eta\}} \frac{|u - v|^2}{\eta^2} \, dx \leq \frac{1}{\eta^2} \text{err}_u^2[v, q, c_1, c_2],
\]

where \( \eta \in (0, \frac{1}{2}) \). Finally, taking the infimum for all \( \eta \in (0, \frac{1}{2}) \) concludes the proof. \( \square \)

In the application, the computational cost to find the optimal \( \eta \) is of the order of the degrees of freedom for the discrete solution and thus affordable. Let us emphasize that the error estimator \( \text{err} \chi \) is not tailored to a specific finite element approach. Indeed, we can project any primal and dual solution onto the spaces \( V = L^2(\Omega) \) and \( Q = H_N(\text{div}, \Omega) \), respectively.

**Remark.** (i) We can obtain an a posteriori error estimate for the segmentation also for intensity values \( \bar{c}_i \), which are only known to be in intervals \([c_i - \epsilon, c_i + \epsilon]\) around some value \( c_i \) for \( i = 1, 2 \) and \( \epsilon > 0 \). Indeed, applying straightforward monotonicity arguments, we obtain the estimate

\[
\text{err}_u^{\text{proj}}[v, q, c_1, c_2] \leq \text{err}_u^2[v, q, c_1, c_2] + \text{err}_u^2[v, q, c_1, c_2]
\]

for

\[
\text{err}_u^{\text{proj}}[v, q, c_1, c_2] := \int \left( \frac{2\mu}{|c_1 - c_2|^2 + 2\sigma^2} \left( u^2 \alpha_{\text{max}} + (1 - u)^2 \alpha_{\text{max}} + |\nabla v| \right)
\]

\[
+ \frac{4}{\sigma_1^2 + \sigma_2^2} \max \left( \frac{\text{div}q}{\sigma_1^2 \alpha_{\text{max}} + \sigma_2^2 \alpha_{\text{max}}}, \frac{\text{div}q}{\sigma_1^2 \alpha_{\text{min}} + \sigma_2^2 \alpha_{\text{min}}}, \frac{\text{div}q}{\sigma_1^2 \alpha_{\text{min}} + \sigma_2^2 \alpha_{\text{min}}} \right) \right) \, dx
\]
provided that \(2\epsilon < |c_1 - c_2|\). Here, \(\theta^{max}(x) = \frac{1}{2} \max\{(c_i + \epsilon - u_0)^2, (c_i - \epsilon - u_0)^2\}\) and \(\theta^{min}(x) = \frac{1}{2} \min\{(c_i + \epsilon - u_0)^2, (c_i - \epsilon - u_0)^2\}\) for \(i = 1, 2\). Thus, for the minimizer \(\tilde{\chi} \in BV(\Omega, \{0, 1\})\) of \(E[v, c_1, c_2]\) the a posteriori estimate
\[
\|\tilde{\chi} - \chi\|_{L^1(\Omega)} \leq \text{err}_{\chi}[v, q, c_1, c_2] := \inf_{\eta(0, \frac{1}{2})} \left(a[v, \eta] + \frac{1}{\eta^2} \text{err}^2_u[v, q, c_1, c_2]\right)
\] (3.3)
holds for all \(v \in V = L^2(\Omega)\) and \(q \in Q = H_N(\text{div}, \Omega)\).

(ii) The optimal intensity values for a given characteristic function \(\chi\) are given in (1.2). For the sensitivity of these values on \(\chi\), we straightforwardly obtain the estimates
\[
|c_1[\chi] - c_1[\tilde{\chi}]| \leq \frac{2l}{\|x - \chi\|_{L^1(\Omega)}} \cdot |c_2[\chi] - c_2[\tilde{\chi}]| \leq \frac{2l}{\|1 - \chi\|_{L^1(\Omega)}}
\] (3.4)
assuming \(\|x - \chi\|_{L^1(\Omega)} < \min\{\|\chi\|_{L^1(\Omega)}, 1 - \chi\|_{L^1(\Omega)}\}\).

(iii) Given the sensitivity results from (i) and (ii) one might ask for an a posteriori error estimate both for \(\chi\) and the intensity values \(c_1, c_2\). In fact, if \((\chi, c_1, c_2)\) is a minimizer of the in general non-convex energy \(E = \int_{\Omega} \frac{1}{2} \frac{1}{2} (c_1 - u_0)^2 \chi + \frac{1}{2} (c_2 - u_0)^2 (1 - \chi) + |D\chi|\Omega)\) and one assumes a priori that each of the initially chosen intensity values is already in some \(\epsilon\) neighborhood of the corresponding \(c_2\)-value, then the estimates (3.3) and (3.4) can be combined to obtain an a posteriori error estimate for the numerical approximation of \((\chi, c_1, c_2)\). Unfortunately, the estimate (3.3) is not sufficiently sharp to ensure that the resulting estimated error in the intensities does actually improve compared to the a priori assumption and a bootstrapping argument could not be applied to further improve the resulting estimates. We refer to Section 6 for an explicit evaluation of the sensitivity of the relaxed solution.

4 Finite Element and Finite Difference Discretization

In this section, we investigate different numerical approximation schemes for the primal and the dual solution of the relaxed problem (2.2) on adaptive meshes and the refinement of the meshes based on the a posteriori error estimates derived in Section 3. In the context of image processing applications with input images usually given on a regular rectangular mesh, an adaptive quadtree for \(n = 2\) (or octree for \(n = 3\)) turned out to be an effective choice for an adaptive mesh data structure. In what follows, we pick up the finite element approach for a variational problem on BV proposed by Bartels [6] and a simplified version of the latter. Furthermore, we consider the widespread finite difference scheme proposed by Chambolle [14]. In all numerical experiments in this paper, we choose \(\Omega = [0, 1]^2\).

(\text{FE}) Finite element scheme on an induced adaptive triangular grid. On the domain \(\Omega\), we consider an adaptive mesh \(\mathcal{M}_h\) described by a quadtree with cells \(C \in \mathcal{M}_h\) being squares, which are recursively refined into four squares via an edge bisection. We suppose that the level of refinement between cells at edges differs at most by one. Thus, on a single edge at most one hanging node appears. Let \(h\) indicate the spatially varying mesh size function on \(\Omega\), where \(h\) on a grid cell \(C\) ranges from an initial mesh size \(2^{-L_{\text{init}}}\) to a finest mesh size \(2^{-L_0}\) (usually determined by the image resolution). For all discretization approaches investigated here, the degrees of freedom are associated with the non-hanging nodes. Let us denote by \(N_v\) the number of these nodes, which will coincide with the number of degrees of freedom of discrete primal functions. The finite element discretization is based on a triangular mesh \(\mathcal{S}_h\) spread over the adaptive quadtree mesh via a splitting of each quadratic leaf cell into simplices \(\mathcal{T}\) ("cross subdivision"). We ask for discrete primal functions \(u_h\) in the space of piecewise affine and globally continuous functions on \(\mathcal{S}_h\), denoted by \(V_h\). Thus, for functions \(v_h \in V_h\) the values at hanging nodes are interpolated based on the
values at adjacent non-hanging nodes, which are associated with the actual degrees of freedom. By \( Q_h = \{ q_h \in V_h : q_h \cdot \nu = 0 \text{ on } \partial \Omega \} \) we denote the discrete counterpart of \( Q \). To accommodate this boundary condition, the boundary nodes are modified after each update of the dual solution in a post-processing step. On \( V_h \), we define discrete counterparts of the continuous functionals \( F \) and \( G \) as follows:

\[
G_h[v_h] := \int_\Omega \frac{1}{2} v_h^2 + v_h \theta_{2,h} - \theta_{1,h} \theta_{2,h} \, dx, \quad F_h[q_h] := \int_{\Gamma} [q_h] \, d\Gamma,
\]

where \( \theta_{i,h} = \mathcal{I}_h(\theta_i) = \mathcal{I}_h(\frac{1}{2}(c_i - u_0)^2) \) for \( i = 1, 2 \) with \( \mathcal{I}_h \) denoting the Lagrange interpolation. In the application on images, we suppose that \( u_0 \in V_h \), where \( V_h \) is the simplicial finite element space corresponding to the full resolution image on the finest grid level \( L_0 \) representing the full image resolution. Furthermore, we consider two different scalar products. On \( V_h \), we take into account the \( L^2 \)-product and on \( Q_h \) the lumped mass product \( (q_h, p_h) \rightarrow \int_\Omega \mathcal{I}_h(q_h \cdot p_h) \, dx \) and identify \( V_h \) and \( Q_h \) with their dual spaces with respect to the \( L^2 \)- and the lumped mass product, respectively. Then, the associated dual operators are

\[
G_h^*[v_h] = \int_\Omega v_h^2 \theta_{1,h} + (1 - v_h^2) \theta_{2,h} \, dx, \quad F_h^*[q_h] = \int_\Omega \mathcal{I}_h([q_h]) \, d\Gamma.
\]

Finally, we define the discrete divergence \( \Lambda_h : Q_h \rightarrow V_h \), \( q_h \rightarrow \mathcal{P}_h \mathrm{div} \, q_h \), where \( \mathcal{P}_h \) denotes the \( L^2 \)-projection \( \mathcal{P}_h : L^2(\Omega) \rightarrow V_h \). Following Bartels [5] and taking into account the above scalar products on \( V_h \) and on \( Q_h \), we obtain for the discrete gradient \( -\Lambda_h^* : V_h \rightarrow Q_h \), \( v_h \mapsto -\Lambda_h^* v_h \), the defining duality

\[
\int_\Omega \mathcal{I}_h(-\Lambda_h^* v_h \cdot q_h) \, dx = \int_\Omega v_h \mathcal{P}_h \mathrm{div} \, q_h \, dx \quad (4.1)
\]

for all \( q_h \in Q_h \) and \( v_h \in V_h \).

**Finite element scheme based on a simple gradient operator.** Instead of the above defined discrete gradient operator \( -\Lambda_h^* \), we alternatively consider the piecewise constant gradient \( \nabla v_h \) on the simplices \( T \) of the simplicial mesh for functions \( v_h \in V_h \). To this end, we choose \( Q_h \) as the space of piecewise constant functions on the simplicial mesh, and take into account the standard \( L^2 \)-product on both spaces. The above definitions of the functionals \( G_h \) and \( F_h \) are still valid. Moreover, \( G_h^* \) remains the same, only \( F_h^* \) changes to \( F_h^*[q_h] = \int_\Omega [q_h] \, dx \). The discrete divergence \( \Lambda_h : Q_h \rightarrow V_h \) is defined via duality starting from the preset discrete gradient as

\[
\int_\Omega \mathcal{I}_h(\Lambda_h q_h v_h) \, dx = -\int_\Omega q_h \cdot \nabla v_h \, dx,
\]

which indeed ensures that \( -\Lambda_h^* v_h = \nabla v_h \). This simplified ansatz leads to a non-conforming iterative solution scheme (see Section 5), since the space of piecewise constant finite elements is not contained in \( H_N(\mathrm{div}, \Omega) \) (cf. [6]). After each modification of the (piecewise constant) dual solution the values on the corresponding boundary cells are set to 0 to satisfy the boundary condition. To apply the derived a posteriori error estimates a projection onto the space \( H_N(\mathrm{div}, \Omega) \) is required. To this end, we replace the solution \( p_h \in Q_h \) by its \( L^2 \)-projection onto the space \( V_h^n \) after each execution of the algorithm.

**Finite difference scheme on a regular mesh.** The finite difference scheme for the numerical solution of functionals on \( BV \) proposed by Chambolle [14] is extensively used in many computer vision applications and applies to image data defined on a structured non adaptive mesh. We compare the a posteriori error estimator for this scheme on non-adaptive meshes with the above finite element schemes on adaptive meshes. To this end, we denote by \( V_h \in \mathbb{R}^{N_v} \) and \( Q_h \in \mathbb{R}^{n N_v} \) nodal vectors on the regular lattice for primal and dual solutions, respectively. Here,
\( \nabla^s = (h^{-1} + 1)^n \), where \( h \) denotes the fixed grid size of the finite difference lattice. Integration is replaced by summation and we obtain the following discrete analogues \( G_h \) and \( F_h \) of the continuous functionals \( F \) and \( G \) as functions on \( \mathbb{R}^{N_v} \) and \( \mathbb{R}^{nN_v} \), respectively:

\[
G_h[V_h] := \sum_{i=1}^{N_v} \left( \frac{1}{2} (V_h^i)^2 + \frac{V_h^i}{h} \theta_{1,h}^i - \frac{1}{\theta_{1,h}^i + \theta_{2,h}^i} \right), \quad F_h[Q_h] := \max_{i=1,\ldots,N_v} I_{B_1}[Q_h]
\]

with \( \theta_{1,h}, \theta_{2,h} \) denoting the pointwise evaluation of \( \theta_1 \) and \( \theta_2 \), respectively, and \( I_{B_1}[Q_h] = 0 \) for \( |Q_h^i| \leq 1 \) and \( +\infty \) otherwise. The associated dual operators for the standard Euclidean product as the duality pairing are

\[
G^*_h[V_h] = \sum_{i=1}^{N_v} (V_h^i)^2 \theta_{1,h}^i + (1 - V_h^i)^2 \theta_{2,h}^i, \quad F^*_h[Q_h] = \sum_{i=1}^{N_v} |Q_h^i|
\]

Finally, we take into account periodic boundary conditions (by identifying degrees of freedom on opposite boundary segments) and use forward difference quotients to define the discrete gradient operator \(-\Lambda_h^* : \mathbb{R}^{N_v} \to \mathbb{R}^{nN_v} \), i.e.

\[
((-\Lambda_h^*)V_h)^j = \left( \frac{V_h^{A(i,j)} - V_h^i}{h} \right)_{j=1,\ldots,n}
\]

where \( A(i,j) \) is the index of the neighboring node in direction of the \( j \)th coordinate vector. As a consequence, the matrix representing the discrete divergence operator \( \Lambda_h : \mathbb{R}^{nN_v} \to \mathbb{R}^{N_v} \) is just the negative transpose of the matrix representing the discrete gradient and thus corresponds to a discrete divergence based on backward difference quotients.

To use the a posteriori error estimate in the finite difference context, we consider as a simplest choice the piecewise bilinear functions \( u_h \) and \( p_h \) uniquely defined by the solution vectors \( U_h \) and \( P_h \), respectively. The boundary condition for \( p_h \) is taken care of in exactly the same way as in the case (FE).

## 5 Duality-Based Algorithms

For the numerical solution of the different discrete variational problems, we primarily use the primal-dual algorithm proposed by Chambolle and Pock [20, Algorithm 1], which computes both a discrete primal and a discrete dual solution to be used in the a posteriori error estimates. Note that we use [20, Algorithm 1] instead of [20, Algorithm 2] even though \( G_h^* \) is uniformly convex. As we will see later, evaluating \((Id + \tau \partial G_h^*)^{-1}\) requires the inversion of a matrix depending on \( \tau \). In Algorithm 1, \( \tau \) is fixed and the inverse can be computed once using a Cholesky decomposition for the sparse, symmetric and positive-definite matrix (for details see [22]), whereas in Algorithm 2 the decomposition of the linear system has to be performed in each iteration. Moreover, using diagonal preconditioning one can improve the convergence speed of Algorithm 1 without any further step size control (see [38]). There is a variety of alternative algorithms to solve this convex minimization problem, e.g. the split Bregman method [27], the semi-implicit dual gradient descent [14], the alternating descent method for the Lagrangian [5, Algorithm A'] or the alternating direction method of multipliers (ADMM) (see [10] and the references therein). For distinct images we compare below the aforementioned algorithm by Chambolle and Pock with a dual gradient descent in terms of the quantity of the error estimator.

Before we discuss the algorithm due to Chambolle and Pock in the more conventional matrix-vector notation, let us rewrite the finite element approaches correspondingly. Let \( N_v = \dim V_h \) (the number of non-hanging nodes) and \( N_q = \dim Q_h \) (for (FE) \( N_q = n N_v \) and for (FE') \( N_q \) is \( n \times \) the number of simplices). In what follows, we will use uppercase letters to denote a vector
of nodal values, e.g. \( V_h^k = v_h (X^i) \) if \( X^i \) is the \( i \)th non-hanging node. The two scalar products are encoded via mass matrices. Here, \( M_h \in \mathbb{R}^{N_v \times N_v} \) represents the standard \( L^2 \)-product on \( V_h \) and is given by \( M_h = \int_{\Omega} \mathbf{v}_h \cdot \mathbf{u}_h \, dx \) for all \( \mathbf{v}_h, \mathbf{u}_h \in V_h \). Furthermore, \( M_h \in \mathbb{R}^{N_q \times N_q} \) is the mass matrix associated with the space \( Q_h \).

For the approach (FE) this is given as the lumped mass matrix with \( \tilde{M}_h \mathbf{P}_h \cdot \mathbf{Q}_h = \int_{\Omega} \mathcal{I}_h (p_h \cdot q_h) \, dx \) for all \( p_h, q_h \in Q_h \), whereas for the discretization (FE') \( \tilde{M}_h \mathbf{P}_h \cdot \mathbf{Q}_h = \int_{\Omega} \rho_h \cdot q_h \, dx \) for all \( p_h, q_h \in Q_h \) defines a classical (diagonal) mass matrix. For the matrix representations \( A_h \) and \( -\Lambda_h^* \) of the discrete divergence and the discrete gradient, respectively, we obtain the relation (cf. [5])

\[
\Lambda_h^* = \tilde{M}_h^{-1} A_h^T M_h . \tag{5.1}
\]

Moreover, for the discretization (FD) we have \( \Lambda_h^* = \Lambda_h^T \). Altogether, the discrete predual energy \( D_h^{rel} : \mathbb{R}^{N_v} \to \mathbb{R} \) and the discrete energy \( E_h^{rel} : \mathbb{R}^{N_q} \to \mathbb{R} \) are defined as follows:

\[
D_h^{rel} [\mathbf{Q}_h] = F_h[\mathbf{Q}_h] + G_h[A_h \mathbf{Q}_h] ,
\]

\[
E_h^{rel} [\mathbf{V}_h] = F_h^*[-A_h \mathbf{V}_h] + G_h^*[\mathbf{V}_h] .
\]

In the case of all finite element discretizations, the functionals \( G_h, F_h, G_h^* \) and \( F_h^* \) are defined using the corresponding functions on the finite element spaces, e.g. \( G_h^*[\mathbf{V}_h] := G_h^*[\mathbf{v}_h] \).

Now, we are in the position to formulate the primal-dual algorithm. For a fixed mesh, fixed intensity values \( c_1, c_2 \) and initial data \((U_0^h, P_0^h) \in \mathbb{R}^{N_v} \times \mathbb{R}^{N_q} \), the Algorithm 1 proposed by Chambolle and Pock [20, Algorithm 1] computes a sequence \((U_k^h, P_k^h)\), which converges to the tuple \((U_h, P_h)\) of the discrete primal and dual solution provided \( \tau \sigma \| A_h \|^2 < 1 \). Indeed, by using

\[
k = 0 ;
\]

while \( \| \mathbf{U}_k^h - \mathbf{U}_k^h \|_{\infty} > \text{THRESHOLD} \) do

\[
\mathbf{P}_{k+1}^h = (\text{Id} + \sigma \partial F_h)^{-1} [\mathbf{P}_k^h - \sigma \Lambda_h^* \mathbf{U}_k^h] ;
\]

\[
\mathbf{U}_{k+1}^h = (\text{Id} + \tau \partial G_h^*)^{-1} [\mathbf{U}_k^h + \tau \Lambda_h \mathbf{P}_k^h + 1] ;
\]

\[
\mathbf{U}_{k+1}^h = 2 \mathbf{U}_{k+1}^h - \mathbf{U}_k^h ;
\]

\[
k = k + 1 ;
\]

end

Algorithm 1: The primal-dual algorithm used to minimize \( E_h^{rel} \).

inverse estimates for finite elements (see [37] for a computation of the constants) the operator norm can be bounded in the case (FE') for \( n = 2 \) as follows:

\[
\| A_h \|^2 \leq 48 (3 + 2 \sqrt{2}) h_{m, n}^{-2} \leq 279.8 h_{m, n}^{-2} ,
\]

where \( h_{m, n} \) denotes the minimal mesh size occurring in \( \mathcal{M}_h \). Moreover, to estimate the operator norm for the case (FE) we use (4.1) and obtain

\[
\| A_h \|^2 = \left( \max_{v_h, v_h, \| v_h \|_{L^2} = 1} \max_{q_h, q_h, \| q_h \|_{L^2} = 1} \int_{\Omega} \mathcal{I}_h (-A_h^* v_h \cdot q_h) \, dx \right)^2 \\
\leq \max_{q_h, q_h, \| q_h \|_{L^2} = 1} \| \mathcal{P}_h \|_{L^2} \| q_h \|_{L^2} \leq \max_{q_h, q_h, \| q_h \|_{L^2} = 1} \| \mathcal{P}_h \|_{L^2} \leq 96 (3 + 2 \sqrt{2}) h_{m, n}^{-2} .
\]

Finally, following [14] we can estimate \( \| A_h \|^2 \leq 8 h_{m, n}^{-2} \) for the discretization (FD).

Suitable stopping criteria are a threshold on the maximum norm of the difference of successive solutions \( \mathbf{U}_k^h - \mathbf{U}_k^h \) (which we apply here) or on the primal-dual gap \( E_h^{rel} [\mathbf{U}_k^h] + D_h^{rel} [\mathbf{P}_k^h] \). To compute the resolvents \((\text{Id} + \partial F_h)^{-1} [\mathbf{Q}_h] \) and \((\text{Id} + \partial G_h^*)^{-1} [\mathbf{V}_h] \) we use a variational ansatz (for
In the case (FD), the resolvent is given by

\[ u \quad Q \quad M \quad L \quad S \quad \begin{bmatrix} h_1 \cr \cdots \cr h_N \end{bmatrix} \]

After each update of the dual variable (5.4) a projection onto \( \tau S \) replacing \( \tau \rho \) we have that

\[ \text{details see [44], i.e. for the resolvent of a subdifferentiable functional } J \text{ with an underlying scalar product } (\cdot, \cdot) \text{ we have that} \]

\[
(Id + \tau \partial J)^{-1}[x] = \arg\min_y (x - y, x - y) + 2\tau J(y).
\]

The resolvent of \( F_h \) for the approaches (FE) and (FD) is given by

\[
(Id + \sigma \partial F_h)^{-1}[Q_h] = \left( \frac{Q_i^h}{\max\{|Q_i^h|, 1\}} \right)_{i=1, \ldots, N_v} (5.2)
\]

with \( Q_i^h = q_h(X^i) \). In the case (FE'), the above evaluation is performed on each cell. For the discretizations (FE) and (FE'), we denote by \( M_h[w_h]U_h \cdot V_h = \int_\Omega w_h v_h \, dx \) the weighted mass matrix for functions \( u_h, v_h \in V_h \) and a weight \( w_h \in V_h \). Then, the resolvent of \( G_h \) reads as

\[
(Id + \tau \partial G_h^*)^{-1}[V_h] = (M_h[1 + 2\tau(\Theta_1, h + \Theta_2, h)])^{-1} M_h (V_h + 2\tau \Theta_2, h) .
\]

In the case (FD), the resolvent is given by

\[
(Id + \tau \partial G_h^*)^{-1}[V_h] = \frac{V_i + 2\tau \Theta_h^i}{1 + 2\tau(\Theta_1, h + \Theta_2, h)} \quad \text{for } 1 \leq i \leq N_v.
\]

In our numerical experiments, we have chosen \( \text{THRESHOLD} = 10^{-8} \).

In the sequel, we consider a projected dual gradient descent for the minimization of \( E_{rel} \) using the discretization (FE), and picking up Chambolle’s semi-implicit gradient descent w.r.t. the dual variable for the ROF model using a finite difference scheme [14]. We remark that the algorithm can analogously be derived for the discretization scheme (FE'). Starting from the first order condition \( \kappa := -(2u\theta_1 + 2(u - 1)\theta_2) \in \partial TV[u] \) for \( E_{rel} \) with \( TV[u] = |Du|(\Omega) \), we can infer \( u \in \partial TV^*[\kappa] \) due to [24, Chapter I, Corollary 5.2], which is the first order condition of the functional

\[
\int_\Omega \frac{1}{4(\theta_1 + \theta_2)} (\kappa - 2\theta_2)^2 \, dx + TV^*[\kappa].
\]

Thus, the unique minimizer is given by \( \kappa = \mathcal{P}_S[2\theta_2] \), where \( \mathcal{P}_S \) denotes the orthogonal projection onto the set \( S = \{ \text{div } p \mid p \in H_N(\text{div}, \Omega), |p|_{L^\infty(\Omega)} \leq 1 \} \) w.r.t. the weighted \( L^2 \)-space with weight \( w = (4(\theta_1 + \theta_2))^\kappa \), denoted by \( L^\kappa(\Omega, w) \). Note that \( w \in L^\infty(\Omega, \mathbb{R}^+) \) due to the assumptions regarding \( \theta_i \). The primal solution is given by \( u = \frac{2\theta_2 - \mathcal{P}_S[2\theta_2]}{2(\theta_1 + \theta_2)} \). For the computation of \( \mathcal{P}_S[2\theta_2] \) we have to solve \( \arg\min_{\xi \in S} \| u - 2\theta_2 \|^2_{L^2(\Omega, w)} \), which is computed by alternatingly performing a gradient descent for the unconstrained problem and a projection onto \( S \). To be precise, for a fixed step size \( \tau > 0 \) the usual gradient descent update scheme reads \( p^{k+1} = p^k + \tau \nabla (w(\text{div } p^k - 2\theta_2)) \). After a multiplication by a test function \( \vartheta \in Q_h \), applying \( \int_\Omega I_h(\cdot) \, dx \) on both sides, replacing \( \nabla \) and \( \text{div} \) by the differential operators \( -\Lambda^*_h \) and \( \Lambda_h \) as introduced in the discretization (FE), respectively, and using (4.1) one obtains

\[
\int_\Omega I_h(p^{k+1}, \vartheta) \, dx = \int_\Omega I_h(p^k, \vartheta) \, dx + \tau \int_\Omega (w(\Lambda_h p^k - 2\theta_2)) \vartheta \, dx .
\]

Let \( \tilde{M}_h \) be the lumped mass matrix, \( L_j U_h \cdot V_h = \int_\Omega u_h \cdot \partial_j v_h \, dx, j = 1, 2 \), for all \( u_h, v_h \in V_h \), and \( W^i_j = w(X^i) \). Then (5.3) implies

\[
[P^{k+1}]_j = [P^k]_j + \tau \tilde{M}_h^{-1} L_j (W^i_h(A_h P^k - 2\Theta_2, h)) \quad \text{for } j = 1, 2 .
\]

After each update of the dual variable (5.4) a projection onto \( S \) is performed (cf. (5.2)). The step size is taken as \( \tau = \gamma \cdot \min_{\xi \in A_M^h} h(\xi) \). The stopping criterion for the resulting algorithm relies on the \( L^\infty \)-distance of two successive dual solutions (in our case, \( \text{THRESHOLD} = 10^{-8} \)). For a
converge analysis of this approach we refer to [12]. In the sequel, we will denote results obtained with the discretization scheme (FE) and this algorithm by (FE_D).

The adaptive mesh refinement is implemented as follows. Given a mesh, fixed intensity values and initial data for the primal and dual solution, we run one of the above algorithms and compute the relaxed discrete primal-dual solution pair \((u_h, p_h)\). In the case of the finite difference approach (FD), we define them as the multilinear interpolation on the cells \(C\) of the regular mesh. The corresponding discrete solution of the original problem (2.1) is then given as \(\chi_h = \chi_{[u_h, \frac{1}{2}]\). Based on \(u_h\) and \(p_h\), we evaluate the local error estimator for every cell \(\mathcal{C}_0\) of the full resolution image grid as follows:

\[
err^2_{u, \mathcal{C}_0}[u_h, p_h] := \frac{2\nu}{(c_1 - c_2)^2} \left( \int_{\mathcal{C}_0} v_h^2 \theta_1 + (1 - v_h)^2 \theta_2 + |\nabla v_h| \right. \\
\left. + \frac{1}{2} \left( \text{div} \, q_h \right)^2 + (\text{div} \, q_h) \theta_2 - \theta_1 \theta_2 \right) \frac{\theta_1 + \theta_2}{\theta_1 + \theta_2} dx.
\]

To this end, a higher order Gaussian quadrature is used. In fact, for (FE), (FE_D) and (FE') we use a Gaussian quadrature of order 4 on the simplices \(T_0\) composing the cell \(\mathcal{C}_0\) on the finest mesh with full image resolution, where the \(\theta_i\) \((i = 1, 2)\) are originally defined, and for (FD) a Gaussian quadrature of order 5 directly on the cells \(\mathcal{C}_0\). The resulting local error estimator for a cell \(\mathcal{C} \in \mathcal{M}_h\) and the global estimator are given as

\[
err^2_{u, \mathcal{C}}[u_h, p_h] = \sum_{\mathcal{C}_0 \subset \mathcal{C}} err^2_{u, \mathcal{C}_0}[u_h, p_h] \text{ and } err^2_{\mathcal{M}}[u_h, p_h] = \sum_{\mathcal{C} \in \mathcal{M}_h} err^2_{u, \mathcal{C}}[u_h, p_h],
\]

respectively. We mark those cells \(\mathcal{C}\) for refinement for which

\[
err^2_{u, \mathcal{C}}[u_h, p_h] \geq \alpha \max_{\mathcal{C} \in \mathcal{M}_h} err^2_{u, \mathcal{C}}[u_h, p_h], \tag{5.5}
\]

where \(\alpha\) is a fixed threshold in \((0, 1)\). Since this method is prone to outliers, we additionally sort all local estimators \(err^2_{u, \mathcal{C}}\) according to their size (starting with the smallest) and mark the cells in the upper decile for refinement as well. For the input data from Figure 1 we refine up to the resolution of the initial image.

6 Numerical Results

In what follows, we show numerical results for four different input images shown in Figure 1. Prior to executing the primal-dual scheme (Algorithm 1) or the dual gradient descent scheme, we choose suitable values for \(c_1\) and \(c_2\) by applying Lloyd’s Algorithm (see [32]) for the computation of a 2-means clustering (with initial values 0 and 1). The resulting initial values are given in Figure 1 together with the values for \(\nu\).

The pixels of the input images are interpreted as nodal values of the function \(u_0\) on a uniform mesh with mesh size \(h = 2^{-L_0}\) (\(L_0 = 9\) for (d), \(L_0 = 11\) else). The algorithm is then started on a uniform mesh of mesh size \(h = 2^{-L_{\text{run}}}\) (\(L_{\text{run}} = 3\) for (d), \(L_{\text{run}} = 5\) else). In all computations we use \(\tau = 10^{-5}\) and \(\sigma = 5 \cdot 10^{-5}\) (Algorithm 1), \(\gamma = 0.05\) for the dual gradient descent and \(\alpha = 0.2\). We perform 10 cycles of adaptive algorithm and refine cells until the depth \(L_0\) of the input image is reached.

We observe slight local oscillations for the finite element approaches (FE), (FE_D) and (FE'), which deteriorate the result of the a posteriori estimator (cf. the numerical results in [5]). Thus, in a post-processing step, we compensate these oscillations prior to the evaluation of the estimator by an application of a smoothing filter. The filter is defined via an implicit time step of the discrete heat equation using affine finite elements on the underlying adaptive mesh, i.e. we apply the operator \((M_h + \epsilon S_h)^{-1}M_h\) to the solutions, where \(S_h\) denotes the stiffness matrix. For the discretizations
(FE) and (FE_D), we choose \( \ell = c \cdot h_{\text{min}}^2 \), where \( h_{\text{min}} \) denotes the minimal mesh size of the current adaptive grid, with \( c = 3 \) and \( c = 6 \) for the primal and the dual solution, respectively. Moreover, in the case (FE’) the smoothing is only applied to the dual solution with parameter \( \ell = 0.75 \cdot h_{a}^{3.9} \), where \( h_{a} \) denotes the average cell size on the adaptive mesh. In our experiments, we observed that these smoothing methods and parameters outperformed other tested choices for the corresponding discretizations. We call the resulting post-processed functions \( \bar{u}_h \) and \( \bar{p}_h \), respectively, and replace the local error estimator by \( \text{err}_{\text{ref}}^{2}[\bar{u}_h, \bar{p}_h] \).

Table 1 lists (scaled) primal and dual energies, \( \text{err}_{\text{opt}}^{2} \), \( \eta_{\text{optimal}} \) (the \( \eta \) value corresponding to the optimal a posteriori error bound for given \( \text{err}_{\text{opt}}^{2} \)) as well as \( \text{err}_{\chi} \) for all input images after the 10th refinement step of the adaptive algorithm. The value of \( \text{err}_{\chi} \) peaks for the application (d) due to the relatively low image resolution. Figure 2 plots the error estimator \( \text{err}_{\chi} \) after each refinement step for all input images and all finite element discretizations. In most of our numerical experiments, the scheme (FE) performs comparably to the discretization (FE_D), but slightly better than the scheme (FE’). For the flower image, the sequence of adaptive meshes and solutions resulting from the adaptive algorithm for the discretization (FE’) is depicted in Figure 3. Figure 4 displays solutions for the discretization (FE’) and the corresponding adaptive meshes together with color coded deciles of \( u_h \), and the graphs of \( \eta \rightarrow \bar{U}_h, \eta \) and \( \eta \rightarrow \text{err}_{\chi} \). Note that the displayed deciles explicitly indicate the sets \( S_{\eta} \) for \( \eta = 0.1, 0.2, 0.3, 0.4 \).

Figures 5 and 6 show the relaxed solution \( u_h \) and the thresholded solution \( \chi_h \) for the input images (b) to (d) using the discretization schemes (FE) and (FD), the corresponding results for (FE_D) are not depicted since they are almost not distinguishable from the results for (FE).

It is known that solutions of the Mumford-Shah problem are in general not unique. We pick up a classical example for this non-uniqueness in Figure 7 with alternating intensity values 0 and 1 on quadrants. We demonstrate the sensitivity of our adaptive scheme with respect to the topology of the segmentation. In fact, we compute a segmentation using the discretization (FE) (with initial intensity values \( c_1 = 1, c_2 = 0 \) and \( \nu = 0.01 \)) for slightly perturbed versions of the original image. I.e. solely the four pixels in the center of the image of resolution \( 2049 \times 2049 \) are either set black or white, respectively. The resulting segmentations are shown in Figure 7 along with the adaptive mesh and the decile plots. The adaptive algorithm is capable to detect properly the decision for one of the two segmentation solutions. The issue of non-uniqueness is closely related to the flatness of the relaxed solution in the center, in particular leading to an increase of the a posteriori error contribution \( A[v, \eta] \).

Moreover, we applied the above methods to an analytic function consisting of a weighted sum of two Gaussian kernels. To this end, in each step the functionals and the error estimator are evaluated on the current adaptive grid and not on a prefixed full resolution grid. The results are shown in Figure 8 (with parameters \( c_1 = 0.495349, c_2 = 0.0568447 \) and \( \nu = 5 \cdot 10^{-3} \)).

Table 1: Rescaled dual and primal energy evaluated on the discrete solution \((u_h, p_h)\), error estimator for the relaxed solution, optimal threshold \(\eta_{optimal}\) computed for \(u_h\) and the resulting a posteriori estimator \(err_\chi\) for the \(L^1\)-error of the characteristic function \(\chi\) (after 10 cycles of the adaptive algorithm).

In addition, we evaluated the sensitivity of the error estimates with respect to variations in the intensity values. Figure 9 shows the function plot of \(\epsilon \rightarrow err_u^2\) \([u_h, p_h, c_1, c_2]\) with fixed primal \(u_h\) and dual solution \(p_h\) obtained with the discretization (FE) after the 10\(^{th}\) iteration for the images (b) and (c). The error estimator for image (b) is less sensitive to small fluctuations in the intensity values compared to image (c) due to the stronger variation of intensity values along the boundary of the segmentation in image (b).

Finally, the proposed discretization schemes were compared in terms of the relative CPU time for the images images (b) and (d) in the last iteration. To enforce comparable conditions the stopping criterion was set to \(|P_{k+1} - P_k|_\infty < 10^{-6}\) and the primal and dual solution were initialized with constant values. In comparison with the discretization scheme (FE), the scheme (FE') required comparable CPU time (image (b): +0.67%, image (d): +6.5%), whereas (FE_D) performed slower for larger images (image (b): +30.4%, image (d): −0.1%).

## 7 Conclusions

We have investigated the a posteriori error estimation for the binary Mumford-Shah model and applied this estimate to three different adaptive finite element discretizations in comparison to a non-adaptive finite difference scheme on a regular grid. The proposed finite element discretizations
in combination with the adaptive mesh refinement strategy lead to a substantial reduction of the required degrees of freedom with error values $\text{err}_u^2$ and $\text{err}_\chi$ of about the same magnitude as for a standard finite difference scheme on a non-adaptive mesh with mesh size equal to the finest mesh size of the adaptive meshes. To improve the resulting estimate of the duality gap $E_{\text{rel}}[v] + D_{\text{rel}}[q]$, the finite element schemes require some oscillation damping smoothing in a post-processing step.

The proposed approach to a posteriori estimates for the binary Mumford-Shah model derived in this paper can be applied to more general problems in computer vision. In fact, the calibration method developed by Alberti, Bouchitté and Dal Maso [1] provides a convex relaxation of non-convex functionals of Mumford-Shah type via the lifting of a variational problem on a $n$-dimensional domain to a minimization problem over characteristic functions of subgraphs in $n + 1$ dimensions. In the context of non-convex functionals in vision, this approach was studied by Pock et al. [39, 40]. Applications of such functionals include the computation of minimal partitions [16, 41], the depth map identification from stereo images or the robust extraction of optimal flow fields [40]. Here, an adaptive mesh strategy is expected to have an even larger pay-off due to the increased dimension.
